Hello,

Did you initiate the build by running install command from upp root directory after extracting:

```
./install
```

It should install following packages on mac using brew:

```
brew install openssl clang-format
```

Also, it is recommended to install XCode. Right now I can not confirm whenever it is needed, but definitely it is worth installing. In the end you need XCode command line tools. Here is the article that describes how to download them.
